**Abstract**

**Introduction:** Herbal medicines are getting more interest because of their cost-effective, eco-friendly attributes and proper reprieve from disease condition. The present study was designed to evaluate the anxiolytic activity potentials in peels of *Citrus reticulata* (Family: *Rutaceae*) in Libya.

**Methods:** The peel of the fruits were separated and subjected to cold extraction using 99% Methanol and hot water extraction. The extracts obtained were screened for anxiolytic activity of extracts at 1.25 to 5 mg/Kg body weight concentrations and were assessed by Elevated Plus Maze.

**Results:** The results revealed that, both extracts treated animals have shown significant anxiolytic activity. From the results it was evident that citrus peel extract of *Citrus reticulata* exhibited significant anxiolytic activity.

**Conclusion:** From the results it was evident that *Citrus reticulata* has prominent activity in terms of parameters assessed in a dose dependent manner.

**Keywords:** Citrus reticulata; Anxiolytic activity; Psychopharmacology

**Introduction**

Human brain is a speculate in itself and is not explored entirely. It is a multifaceted gathering of interacting neurons and nuclei that control their own and each other’s activities in a dynamic manner, usually throughout chemical neurotransmission. Psychopharmacology is the scientific learning of the effect’s drugs encompass on mood, thinking, behavior and sensation. It is different from neuro-psychopharmacology, which studies drug-induced alterations in the functioning of cells in the nervous system [1,2]. Two-thirds of the psychotic, depressed, or anxious patients react to the currently available treatments, but the enormity of improvement is not very significant.

The majority of the drugs for these conditions used these days have adverse side effects so the need for better-tolerated, newer and more efficacious treatments is enduring far above the ground [3,4]. The main use of sedative-hypnotic and anxiolytic drugs is to promote calmness (sedatives or anxiolytics) or to create sleep (hypnotics–sedative). Human are exposed to states of restlessness and emotional tension. Anxiety always accompanies many medical and surgical conditions, and it is frequently an indication of psychiatric illness. When the symptoms turn into insufferable or interfere with the treatment of the underlying disease, and if counseling is not enough, drug treatment can be used to help patients manage with their anxiety [5]. There are many medicines are used to treat many psychotherapy and pharmacotherapy illness such as benzodiazepines, azapirones, and antidepressants and others [6].

*Citrus reticulata* (*Rutaceae*) is commonly known as naringin or Sentra (orange). It is a small spiny tree with thick top of slim branches, extensively grown in Egypt, Tunisia and Libya [7]. Mandarin is a collection name for this class of orange with thin, loose peel. The name ‘tangerine might be applied as an interchange name
to the entire group, but in trade, it is usually limited to the types with red-orange skin. The fruit has aphrodisiac, laxative, tonic properties and astringent [8,9]. It is also used to alleviate vomiting [10,11]. The fruit peel controls the skin moisture, rough and softens hard skin and possess a cleaning effect on oily skin [12]. Chemical composition of the volatile oil of the fruit peels of this species has been reported [13-17]. The effects of the volatile oil of C. reticulata has been studied against Saccharomyces cerevisiae [18], pathogenic fungi, Penicillium larvae, Schistosoma mansoni, Aspergillus flavus, and other microorganisms [19-24]. The volatile oil of C. reticulata also demonstrates the anticancer activity [25-27]. The present paper describes the neuropharmacological Activities of methanolic and aqueous extracts of Citrus reticulata (Rutaceae) fruit peels of the essential oil of the fruit peel of C. reticulata of Tripoli region.

**Materials and Methods**

**Collection of plant material and Preparation of aqueous extract**

The oranges were bought from a shop in Tripoli (February 2019). The Citrus reticulata was identified and authenticated by a botanist. Orange rinds were peeled off carefully with the help of a sharp razor blade. Each rind sample was cut into smaller pieces and 30g mass of the sample was taken. The sample was initially rinsed with distilled water. The fresh peels (30 g) were added to 30 ml hot distilled water. In addition, another 30 g of the fresh peels were macerated in cold 99% methanol for three hours. After 3 hours of maceration at room temperature (28°C), the mixture was then was filtered under vacuum and the filtrate was stored at 4°C and used to treat animals as needed [28].

**Experimental models**

Swiss albino mice of either sex weighing about 18–28g (2–2.6-month-old) used for experimental purpose. They were housed in polycarbonate cages in the air-conditioned room with the temperature maintained at 25±2 °C, and 12 h alternating light and dark cycles. The mice were provided with a nutritionally adequate diet and drinking water ad libitum throughout the study. Approval by the Animal Ethics Committee for the experimental procedures obtained.

**Acute toxicity study**

Acute toxicity was generally carried out for the determination of LD50 value in experimental animals. The aim of performing acute toxicity study is for establishing therapeutic index of a methanolic and aqueous extracts of Citrus reticulata and to ensure safety in-vivo. Acute toxicity test was performed in mice. All animals were fasted overnight before treatment and were given food one hour after aqueous and methanolic extracts. General behavior was also observed at 0.5, 1, 8, 12 and 24 h after administration. The number of animals that died after administration was traced daily for 7 days [29,30].

**Elevated plus-maze test**

Elevated plus-maze is simple apparatus to study neuroprotective effects [31,32] and anxiolytic responses produced by the test drugs. It is used to test almost all types of anxiolytic agents. Exposure of animals to novel maze alley suggests an approach-avoidance conflict which is stronger in open arm as compared to enclosed arm. Rodents (rats and mice) have an aversion for high and open space and prefer enclosed arm, consequently, spend a greater amount of time in enclosed arm. When animals enter open arm, they freeze, become immobile, defecate and show fear-like movements [33]. The cortisol plasma level is increased, as a true reflection of anxiety. Major advantages of this test procedure are:

- It is less time consuming, simple and quick
- No noxious stimuli (light or sound) or prior training is required, and
- It is conventional and consistent procedure for studying anxiety response as well as anxiolytic action of drug [34,35].

Animals were weighed, numbered, and divided into five groups, each consisting 6 mice. One group was used as control (saline), second for standard drug (diazepam) treatment; groups 3-6 for aqueous Citrus reticulata extract treatment (1.25, 2.5, 3.75, 5.00 mg/kg, intra-peritoneally) and groups 7-10 for methanolic Citrus reticulata extract treatment (1.25, 2.5, 3.75, 5.00 mg/kg, intra-peritoneally). Animals were placed individually in the center of the maze, head facing toward open arm and stopwatch was started. The following parameters were noted for 5 min.

i. First favorite of mouse to open or closed arm.

ii. Number of entries in open arm (an arm entry defined as the entry of four paws into the arm).

iii. Average time each animal spends in open arm (Average time = total duration in the arm/number of entries) was estimated.

Saline and diazepam were injected to the control and standard groups respectively. Citrus reticulata extracts were injected to the test groups. After thirty minutes, animals were located individually in the center of the maze. Lastly, a comparison of the preference of the animals to open or enclosed arm, average time spent in open arm and the number of entries in open arm in each group were determined and recorded [36].

**Statistical Analysis**

Data were expressed by mean ± standard error mean. For comparison among the groups, we used analysis of variance with multiple comparisons by post-hoc Dunnett t-test method. The statistical significance of differences between the control and experimental groups was assessed by Dunnett’s two-sided t-tests (post-hoc tests). Statistical analysis was done using Statistical Package for the Social Sciences for windows (version 17.0, SPSS Inc., Chicago, USA). Statistical significance was considered P < 0.05 level.

**Result**

**Acute toxicity study**

With the growing amount of research about naringin as a component of the orange and its potential utilize within the pharmaceutical and food industries, illuminating its toxicological outline
becomes increasingly significant. In the present study, the Citrus reticulata extracts were found to be safe up to 200 mg/kg orally. This present study is compared with other previous studies in which an oral single dose of 16 g/kg of naringin did not produce acute oral toxicity in rats [37].

Tables 1 & 2 summarized the number of entries (open and total) of mice in elevated plus maze and the time spent by mice on elevated plus maze in open and closed arms, respectively.

### Discussion

Recently, interests in powerful pharmacological properties and clinical applications of natural products for replacing synthetic drugs are rising. Despite of chief scientific and technological development in combinatorial chemistry, drugs obtained from natural products still create a huge contribution to drug discovery today. The citrus plant belongs to the family Rutaceae, comprising of about seventeen species found all over the tropical, subtropical and temperate regions [38,39]. Among the species, Citrus indica, Citrus ichangensis, Citrus latipes, Citrus macroptera, Citrus jambhiri, Citrus aurantium, and Citrus reticulate are the most common. The genus citrus includes special essential fruits such as orange, mandarins, limes, lemons, and citrons grapefruits [38]. Even though, there are many groups of plants that are crucial in phytochemistry, citrus plantation has been assumed to be a valuable target for commercial agricultural and industrial practices in the world [40]. About 37 major components were identified from Citrus reticulata [41,42], and the major components were geraniol (19.0%), geranyl acetate (3.9%), limonene (46.7%), nerol (14.5%), nerol (2.3), β-caryophyllene (2.6), citronellal (1.3%), geraniol (3.5%), and neryl acetate (1.1%). Citrus oil also composed of aldehydes and esters being the lowest percentage components and about 97% monoterpenes with alcohols, with values ranging between 1.8 to 2.2% [43]. It has been reported that the identify of about 16-27 chemical constituents in the peel essential oil of C. reticulata was allocated including limonin and naringin and others [44-47].

Naringin is found in many plants. It is a flavonoid and was believed to relieve anxiety at the dose level below 3mg/kg when given intra-peritonally. At high doses it has been reported to cause sedation but no muscle relaxant property [48]. The anxiolytic effect of naringin has been studied using mice 6-8 weeks old and 30g to 35g weight and the anxiolytic effect was confirmed using elevated plus maze and locomotors activity and these results are in consistency with the results obtained in Table 1 & 2 [48]. It has been reported that the diazepam 2 and 10 mg/kg dose were used which increased the number of open arm entries and percent of time spent in open arm as compared to saline control [48] and these results also are in consistency with the results obtained in Table 1 & 2.

The results obtained in Table 1 & 2 are also in agreements with studies done by Marder et al. [49,50], which have shown that nar-

possess dose-dependent anxiolytic activity.

extract exerts above effects. Further studies are needed to separate and confirm the active components and its effect on anxiety.
