Abstract

Diarrheal diseases are a major public health problem in developing countries. *Anogeissus leiocarpus* (DC.) Gill. & Perr (Combretaceae) is used in Africa and particularly in Cameroon for the empirical treatment of diarrhea. The present study was undertaken to evaluate the effects of aqueous extract of leaves of *Anogeissus leiocarpus* on castor oil-induced diarrhea in rats. Diarrhea was induced by administering 10 mL/kg body weight of castor oil orally to male rats. The determination of effective doses was made by assessing the weight and frequency of diarrheal stool of different doses of the extract (25 mg/kg, 50 mg/kg, 100 mg/kg, 200 mg/kg and 400 mg/kg). The effects of the aqueous extract of *Anogeissus leiocarpus* on intestinal transit were determined with an activated charcoal meal in rats. The effects of the aqueous extract of *Anogeissus leiocarpus* on intestinal secretion were evaluated by measuring the volume of the intestinal content and by dosing the electrolytes (Na⁺, K⁺ and Cl⁻) in the intestinal content by the colorimetric method.

Castor oil-induced diarrhea was significantly inhibited ($P < 0.01$) by 59.93%; 69.39%; 68.88%; 67.60% and 75.00%, respectively in the animals treated with the aqueous extract of the leaves of *Anogeissus leiocarpus* at doses of 25 mg/kg, 50 mg/kg, 100 mg/kg, 200 mg/kg and 400 mg/kg. The intestinal transit was inhibited significantly ($P < 0.01$) by 29.34%, 31.35% and 43.29%, respectively of the aqueous extract of *A. leiocarpus* at doses 25 mg/kg, 50 mg/kg and 100 mg/kg. The volume of the intestinal content was decreased significantly ($P < 0.01$) by 53.91%, 83.43% and 72.17%, respectively in the animals treated with the extract at doses 25 mg/kg, 50 mg/kg and 100 mg/kg as well as the concentration of electrolytes. These results would justify the use of leaves of *Anogeissus leiocarpus* in the treatment of diarrhea in traditional medicine.

Keywords: *Anogeissus leiocarpus*; Diarrhea; Castor oil; Male rat

Introduction

Diarrheal diseases are a major public health problem in developing countries [1,2]. Diarrhea is intestinal disorders characterized by the passage of three or more loose and/or liquid stools daily and is one of the leading causes of mortality and morbidity in developing countries [3,4]. The pathophysiology of diarrhea is due to increased secretion and decreased fluid absorption leading to increased fluidity, stool volume and frequency, excessive loss of body water and electrolytes [5]. According to the WHO [6], there

are approximately 2 billion cases of diarrhea per year worldwide. It is the leading cause of death for children under five (05) with about 1.5 million children each year [7], the third leading cause of death among infectious diseases at all ages [8,9], and the fifth leading cause of premature death worldwide [6]. The probability of developing diarrhea is 39.1% for an inhabitant of sub-Saharan Africa, compared with 7.2% in developed countries [10]. In Cameroon, the prevalence of diarrhea is 18.9%, with about 19.7% in rural

areas [11]. The management of diarrheal diseases is very expensive and varies from CFAF 1.6 billion per year for clinical consultation services to CFAF 2.6 billion for hospitalizations [12]. In addition, synthetic chemicals such as diphenoxylate, loperamide and antibiotics used in the treatment of diarrheal diseases have harmful side effects for the body [13].

To cope with the damage caused by diarrhea in developing countries, a diarrhea program has been put in place the World Health Organization (WHO) which involves the use of traditional medicinal plants [4]. Many hopes remain hidden in the secrets of medicinal plants and according to WHO, in 2013, more than 80% of African populations use traditional medicine and pharmacopoeia to deal with health problems [14,15]. More than two-thirds (2/3) of the world's medicinal plant species are found in tropical Africa [14,15]. Some of these plants are used in the treatment of diarrheal diseases. We can mention among others: *Zygophyllum gaetulum* [16], *Erythrina senegalensis* [17], *Pterocarpus erinaceus* [18], *Holarrhenna antidysenterica* [19], *Oxalis barrelieri* [20]. In Cameroon, maceration of the leaves of *Anogeissus leiocarpus* is used empirically for diarrheal diseases or dysentery treatment [21]. *Anogeissus leiocarpus* (DC.) Guill. and Perrot, belonging to the Combretaceae family, is a deciduous tree species up to 15 to 18 m tall and up to 1 m in diameter. It grows in dry forests and the forest gallery [22,23]. *Anogeissus leiocarpus* is used for the treatment of malaria [24], helminthiasis [25], leishmaniasis [26] and trypanosomiasis [26] in Ivory Cost and in Nigeria. The extract of this plant is a powerful antioxidant and hepatoprotective [27-29]. The preliminary phytochemical screening of stem and bark extracts of *Anogeissus leiocarpus* shows the majority of secondary metabolites consisting of tannins, flavonoids, terpenes and saponins [21,30]. No scientific work has so far evaluated the antidiarrheal activity of this plant. The main objective of this work is to evaluate the activities of *Anogeissus leiocarpus* leaves aqueous extract on castor oil-induced diarrhea in rats.

Material and Methods

Plant material

Fresh leaves of *Anogeissus leiocarpus* were collected between 8:00 and 10:00 AM in Mban-Rey (Northern Region of Cameroon) in June 2018 and identified in the Department of Biological Sciences, Faculty of Science of University of Ngaoundere Cameroon by Professor Pierre Marie Mapongmetsem. The leaves of *Anogeissus leiocarpus* were washed with water, shade-dried and crushed. The powder (180g) was macerated in distilled water (1.8 L) for 72h. After a maceration period, this was then filtered with Whatman No. 3 filter paper and the filtrate was frozen at -35 °C and then lyophilized with the freeze-dryer (CHRIST, ALPHA 1-2. LD. plus) to yield 29.14g (16.19%) of greenish-colored extract.

Experimental Animals

The experimental animals were male Wistar albino rats (90-160g), 8 to 12 weeks old. Before the experiment, these rats were acclimated to the Laboratory of Medicinal Plants, Health and Galenic Formulation of the Department of Biological Sciences of University of Ngaoundere for three weeks in the laboratory environmental

conditions (24 °C-26 °C and 12h light/12h darkness). Experiments on animals have been carried out according to the European Union guidelines on animal care (EEC Council No. 86/609) [31] adopted in Cameroon by its Ministry of Scientific Research and Innovation. Rats housed in metabolic cage and their diet consisted of a mixture of corn flour (60%), palm oil (3%), fish meal (12%), soy flour (15%) and a little salt that is in granule form [32].

Castor oil-induced diarrhea test in rat

Thirty-five (35) male Wistar albino rats (90-160g) divided into seven (7) groups of five (5) animals each were fasted for eighteen (18h) with free access to water before the start of the experiment. To induce the diarrhea, castor oil was given per os (10 mL/kg bw) to all animals. After diarrheal induction, each animal was placed individually in cages lined with wathman No 3-filter paper. Thirty (30) minutes later, animals from diarrheal control (DC) group received distilled water (10 mL/kg bw), animals from treated control group (Lop5) received loperamide (MH/DRUGS/KD-699, PALGHAI 401-404) (5 mg/kg bw) and animals from five test groups received one of the aqueous leaf extract of *Anogeissus leiocarpus* at doses 25 (AIAE25); 50 (AIAE50); 100 (AIAE100); 200 (AIAE200) or 400 (AIAE400) mg/kg bw orally. The filter paper was changed every hour for 5 hours. Every hour, the stools were removed and weighed [33]. The number and mass of diarrheal and total stools were recorded. The stool emission frequency (SEF) and the percentage inhibition (I) of diarrhea in each group of treated animals were calculated respectively according to the following formulas:

$$SEF = \frac{\text{Total Number of Stool}}{\text{Time}(5h)} \quad (1)$$

$$I(\%) = \frac{(SMDC - SMDT)}{SMDC \times 100} \quad (2)$$

Where, SEF: Stool Emission Frequency, I: Inhibition; SMDC: Stool Mass of Diarrheal Control, SMDT: Stool Mass of Diarrheal Test.

Gastrointestinal motility test in rat

Five (05) groups of five (05) rats each were fasted for eighteen (18) hours with free access to water before the start of the experience. After the fasting period, all animals were weighted, animals in the normal control (NC) group received distilled water (10 mL/kg bw), animals in the treated control group (AT0.3) received Atropine sulfate (Yanzhou Xierkangtai Pharma.Co., Ltd., Jiuguan Bei, Yanzhou, PR China) 0.3 mg/kg ip, and the animals in the test groups received orally one of the aqueous extract doses of *Anogeissus leiocarpus* 25 mg/kg (AIAE25); 50 mg/kg (AIAE50) or 100 mg/kg (AIAE100) respectively. Thirty (30) minutes after administration of these treatments, each animal received orally 2 mL of charcoal meal (5% activated charcoal by 5% gum acacia) as peristaltic marker. Thirty (30) minutes later the animals were sacrificed by cervical dislocation and the abdomen was opened using forceps. The intestine was removed, the total length of the small intestine (TLSI), and the distance covered by the charcoal meal in the small intestine (DCCM) were measured. The peristaltic index (PI) was calculated by the following formula [4,34,35]:

$$PI = \frac{DCCM}{TLSI} * 100 \quad (3)$$

Where: DCCM: Distance Covered by a Charcoal Meal in the small intestine; TLSI: Total Length of the Small Intestine.

The inhibition was determined by the following formula:

$$I(\%) = \frac{(PIc - PI_t)}{PIc} * 100 \quad (4)$$

Where, PIc: Peristaltic Index in the normal Control; PI_t: Peristaltic Index in the Test Group.

Castor oil-induced interpooling test in rats

Six (6) groups of five (5) rats each fasted for eighteen (18) hours with free access to water were used. After fasting period, all animals were weighted, animals in the normal control (NC) and diarrheal control (DC) groups received orally distilled water (10 mL/kg bw), the animals in the treated control group (Lop5) received loperamide (5 mg/kg bw), and the animals of the test groups, respectively received one of the doses of *Anogeissus leiocarpus* aqueous extract 25 mg/kg (AIAE25); 50 mg/kg (AIAE50) or 100 mg/kg (AIAE100). Thirty (30) minutes after treatment, each animal received orally castor oil (10 mL/kg bw), with the exception of animals in the normal control (NC) group. An hour later, the animals were sacrificed by cervical dislocation, the abdomen was opened, the small intestine (from the pylorus to the caecum) was removed, weighed, and its content was emptied into a graduated tube, and finally the gut was weighed [18,33,36,37]. The volume of intestinal contents was measured and stored in the fridge for sodium ion (Na⁺), potassium ion (K⁺) and chloride ion (Cl⁻) measurements, and the determination of the osmotic gap. The inhibition was determined by the following formula:

$$I(\%) = \frac{VICDC - VICTG}{VICDC} * 100 \quad (5)$$

Where, VICDC: Volume of Intestinal Content of Diarrheal Control; VICTG: Volume of Intestinal Content of Test Group.

Sodium ion (Na⁺), potassium ion (K⁺), and chloride ion (Cl⁻) measurements were made using the colorimetric method using the kits [(LIQUIZYME SODIUM, BEACON DIAGNOSTIICS PVT.LTD., 424, NEW GIDC, KABILPORE, NAVSARI-396 424. INDIA); (LIQUIZYME POTASSIUM, BEACON DIAGNOSTIICS PVT.LTD., 424, NEW GIDC, KABILPORE, NAVSARI-396 424. INDIA); (SGM Italia-Via Pindaro 28C-Roma), respectively], according to the manufacturer's protocol. The osmotic gap was calculated according to the formula:

$$OG = 290 - 2X([Na^+] + [K^+]) \quad [38] \quad (6)$$

Statistical analysis

Datas were expressed as mean±SEM. Statistical significance was determined by the one-way analysis of variance (ANOVA) followed by Dunnett's test using the software Graph Pad in Stat. Differences were considered significant at p <0.05.

Results

Effects of *Anogeissus leiocarpus* leaves aqueous extract on stool frequencies and mass in rats

After castor oil administration, the animals became calm, less mobile and folded themselves with erect hairs. Diarrheal animals treated with different doses of the extract and loperamide gradually regained their mobility during treatment. The first diarrheal stool usually appeared in the first hour and rarely in the second hour of treatment. These stools were either pasty, liquid (diarrhea stool) or molded (normal stool) (Figure 1).

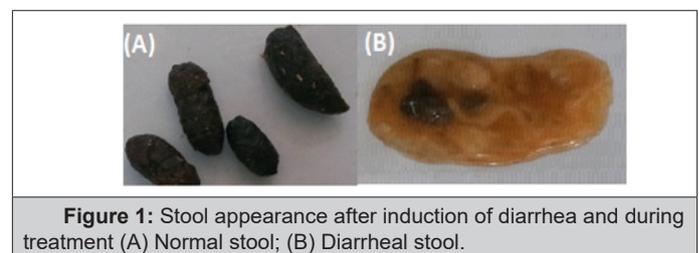

Figure 1: Stool appearance after induction of diarrhea and during treatment (A) Normal stool; (B) Diarrheal stool.

Table 1: Effects of *Anogeissus leiocarpus* leaves aqueous extract on stool frequencies and on stool mass in rats.

Group	DSF (N/h)	TSF (N/h)	DSM (g)	TSM (g)

Data are mean ± S.E.M (n=5). DC: diarrheal control; Lop5: Loperamide 5 mg/kg; AIAE25: *A. leiocarpus* aqueous extract 25 mg/kg; AIAE50: *A. leiocarpus* aqueous extract 50 mg/kg; AIAE100: *A. leiocarpus* aqueous extract 100 mg/kg; AIAE200: *A. leiocarpus* aqueous extract 200 mg/kg; AIAE400: *A. leiocarpus* aqueous extract 400 mg/kg; DSF: Diarrheal stool frequency, TSF: Total Stool Frequency, DSM: Diarrheal Stool Mass, TSM: Total Stool Mass.

Significant difference: *P <0.05, **P <0.01 vs DC.

Five (5) hours after diarrheal induction, diarrheal control emitted 2.35 ± 0.39 g stool with a frequency of 4.20 ± 0.38 stools/hour. Different doses of aqueous extract of *A. leiocarpus* reduced significantly ($P < 0.01$) the number and mass of diarrheal stools in the treated animals. The frequencies of these diarrheal stools were: 4.20 ± 0.38 , 1.60 ± 0.93 , 0.95 ± 0.32 , 1.80 ± 0.80 , 1.20 ± 0.59 , 1.80 ± 0.92 , and 0.80 ± 0.38 stool/h, respectively, in diarrheal controls, lopera-

mid-treated rats, and rats treated with *A. leiocarpus* aqueous extract at doses of 25, 50, 100, 200 and 400 mg/kg bw (Table 1).

The inhibition rate of diarrheal stool mass was significant ($P < 0.01$): 65.14%, 59.93%, 69.39%, 68.88%, 67.60% and 75.00% respectively for Lop5, AIAE25, AIAE50, AIAE100, AIAE200 and AIAE400 (Figure 2).

Data are mean \pm S.E.M (n=5). Volumes of intestinal contents were 0.46 mL, 2.3 mL, 0.38 mL, 1.06 mL, 0.38 mL and 0.66 mL, respectively in normal control group (NC), diarrheal control (DC) group, the rats treated with loperamide 5 mg/kg (Lop5) and the test groups treated with *A. leiocarpus* aqueous extract at doses 25; 50 and 100 mg/kg bw. The mass difference between the untrimmed small intestine and the empty small intestine were 1.14±0.12 g, 2.44±0.28 g, 0.78±0.11 g, 1.48±0.34 g, 0.69±0.07 g, and 1.06±0.16 g, respectively in normal control group (NC), diarrheal control (DC) group, the loperamide-treated group (Lop5) and the test groups treated with *A. leiocarpus* aqueous extract at doses 25; 50 and 100 mg/kg bw. Inhibitions of secretion were 85.04%, 53.91%, 83.43%, 72.17% respectively in the animals treated with loperamide 5 mg/kg bw (Lop5), the test groups treated with *A. leiocarpus* aqueous extract at doses 25; 50 and 100 mg/kg (Table 3).

Activity of *Anogeissus leiocarpus* leaves aqueous extract on intestinal secretion the of electrolytes in rats

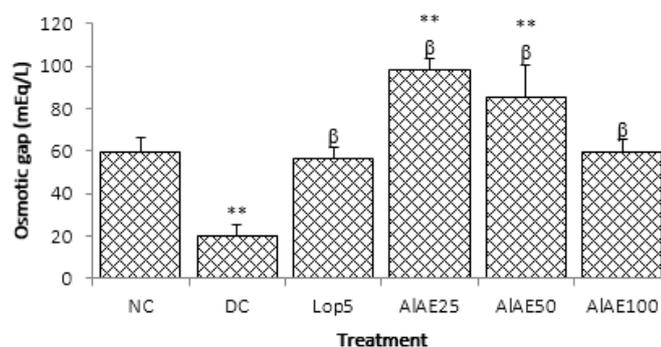

The following electrolytes were measured in the contents of the small intestine: sodium ions, potassium ions and chloride ions.

In diarrheal control, sodium ion concentration was 132.03±2.59 mEq/L. These sodium ions decreased significantly ($P < 0.01$) in the animals treated with the aqueous extract of the leaves of *Anogeissus leiocarpus* and were 92.61±2.58 mEq/L, 98.24±7.54 mEq/L and 108.92±3.07 mEq/L, respectively, with the doses 25 mg/kg bw, 50 mg/kg bw, and 100 mg/kg compared to animals treated with loperamide (110.67±2.62 mEq/L). The concentration of potassium ions was 7.69±1.81 mEq/L, 3.01±0.07 mEq/L, 5.94±0.29 mEq/L, 3.33±0.10 mEq/L, 3.97±0.12 mEq/L, and 6.19±0.12 mEq/L, respectively in normal control group (NC), diarrheal control (DC) group, rats treated with loperamide (Lop5) and the test groups treated with *A. leiocarpus* aqueous extract at doses 25; 50 and 100 mg/kg bw. Concerning chloride ions, the concentration was 101.20±1.65 mEq/L, 109.80±0.04 mEq/L, 106.31±0.86 mEq/L, 104.43±0.29 mEq/L, 104.85±0.31 mEq/L, and 105.11±0.04 mEq/L, respectively in normal control group (NC), diarrheal control (DC) group, rats treated with loperamide (Lop5) and the test groups treated with *A. leiocarpus* aqueous extract at doses 25; 50 and 100 mg/kg bw (Table 4).

Table 4: Effects of *Anogeissus leiocarpus* leaves aqueous extract on concentration of electrolytes in the intestinal contents.

Figure 3: Osmotic gap in castor oil-induced diarrhea in rats.

The osmotic gap was 59.24, 19.91, 56.77, 98.11, 85.58 and 59.79 respectively in the normal control (NC), diarrheal control (DC), rats treated with loperamide 5 mg/kg bw (Lop5) and the test groups

treated with *A. leiocarpus* aqueous extract at doses 25 (AIAE25); 50 (AIAE50) and 100 (AIAE100) mg/kg bw (Figure 3).

Discussion

Diarrhea is defined as fecal urgency and incontinence associated with an imbalance between intestinal absorption and secretion mechanism often accompanied by hypermotility, resulting in excessive loss of water and electrolytes in the feces [39]. The study of the effect of aqueous extract of leaves of *A. leiocarpus* on experimental diarrhea induced by castor oil in rats showed a significant reduction in the number, the mass and frequency of diarrheal stools, an inhibition of the peristaltic index, a decrease in the volume of intestinal contents and the intestinal secretions of the electrolytes. Castor oil contains ricinoleic acid which stimulates intestinal peristalsis, stimulates gastrointestinal secretion and irritates the intestinal mucosa [5]. Ricinoleic acid also stimulates epithelial cells to produce nitric oxide and adenylate cyclase that lead to the production of prostaglandin-induced diarrhea [40]. Therefore, inhibition of prostaglandin biosynthesis is considered to inhibit ricinoleate-induced diarrhea [41]. The aqueous extract of *Anogeissus leiocarpus* leaves inhibited castor oil-induced diarrhea. These effects would be justified by the presence of compounds such as flavonoids, alkaloids [42] and tannins [21,30].

The extract also inhibited intestinal secretion as well as intestinal transit. Inhibition of intestinal transit by the extract was similar to that of atropine sulfate 0.3 mg/kg. Atropine sulfate slows intestinal transit thanks to its anticholinergic effect which blocks the muscarinic receptor [43]. This extract, like Atropine, acts as a muscarinic antagonist by preventing the mobilization of Ca^{2+} ions responsible for muscle contraction [44,45] by blocking the muscarinic receptors responsible for the formation of IP₃, causing the increase in intracellular calcium [46]. It would also act, either by blocking the membrane calcium channels. The physiological consequence is the inhibition of intestinal peristalsis, which would increase the intestinal transit time [2]. The effect of *A. leiocarpus* aqueous extract on intestinal transit could then result from a partial capacity of the extract's antidiarrheal activity on muscarinic receptor function and/or possibly other mechanisms that would lead to the inhibition of intracellular calcium mobilization such as inhibition of IP₃ and ricinoleic acid-induced prostaglandin in beaver oil.

Depending on the fecal osmotic gap, there are two types of diarrhea: secretory diarrhea so the osmotic gap is less than 50 mEq/L and osmotic diarrhea so the osmotic gap is greater than 125 mEq/L. Normal values of fecal osmotic gap are between 50 mEq/L and 125 mEq/L [38,47]. The fecal osmotic gap in diarrheal controls is less than 50 mEq/L, which clearly shows that castor oil-induced diarrhea in rat is a good secretory diarrhea. However, in animals treated with the extract or the loperamide, the fecal osmotic gap is greater than 50 mEq/L and less than 100 mEq/L. The aqueous extract of *Anogeissus leiocarpus* inhibits castor oil-induced diarrhea by inhibiting the secretion of water and electrolytes. Loperamide has an agonist action on μ -receptors of opioid in the intestine [48,49]. Several published studies have clearly shown antisecretory action of loperamide via various mechanisms. Loperamide therefore binds not only to the opioid μ receptor but also to the δ receptor of the enterocyte. This results in a decrease in cAMP production in the epithelial cells of the intestine. This reduces hypersecretion

of electrolytes in case of diarrhea [48,49]. In addition, loperamide inhibits the release of acetylcholine and prostaglandins since these two substances are known secretagogues (substances that, by stimulating cAMP, cause the secretion of ions) [48]. We can say that our extracts would act in the same mechanism to reduce or treat diarrhea by reducing the volume of the secretion of the intestinal contents and electrolytes.

Conclusion

From the results obtained, we can conclude that the aqueous extract of *Anogeissus leiocarpus* leaves has antidiarrheal properties by inhibiting intestinal peristalsis, gastrointestinal secretion of water and electrolytes. These results would justify the use of this plant in traditional medicine for the treatment of diarrhea.

Acknowledgments

Professor Njintang Yanou Nicolas is gratefully acknowledged for freeze-drying our extract.
